

Problem 19.1

The conversion of A to B takes place in an aqueous solution in an adiabatic batch reactor. The reactor is charged with 1200 L of a 2 M solution of A at 300 K. The heat capacity of the solution of a whole can be taken to equal $1.0 \text{ cal mL}^{-1} \text{ K}^{-1}$. The heats of formation of A and B may be taken to equal -75 and $-82 \text{ kcal mol}^{-1}$, respectively, and the heat of reaction may be assumed to be independent of temperature. Calculate the time required to reach 80% conversion and the final temperature. The reaction is first order in A and the rate coefficient obeys the Arrhenius expression with a pre-exponential term equal to $2.4 \times 10^8 \text{ s}^{-1}$ and an activation energy of $15.3 \text{ kcal mol}^{-1}$.
